3 GUI and Dialogue box

3.1 GUI in Python

- Objectives of this section includes how to develop graphical user interfaces by writing some Python GUI examples using the Tkinter package.
- Tkinter package is shipped with Python as a standard package, so we don't need to install anything to use it.
- Tkinter package is a very powerful package. If you already have installed Python, you may use IDLE which is the integrated IDE that is shipped with Python, this IDE is written using Tkinter. Sounds Cool!!
- We will start by creating a window then we will learn how to add widgets such as buttons, combo boxes, etc, then we will play with their properties, so let's get started.

3.2 Create your first GUI application

First, we will import Tkinter package and create a window and set its title:

```
from tkinter import *
window = Tk()
window.title("Welcome to Like Kef app")
window.mainloop()

The result will be like this:

Wel... — 

Wel... — 

X
```

The last line which calls the mainloop function, this function calls the endless loop of the window, so the window will wait for any user interaction till we close it. If you forget to call the mainloop function, nothing will appear to the user.

3.3 Create a label widget

To add a label to our previous example, we will create a label using the label class like this: lbl = Label (window, text="Hello")

Then we will set its position on the form using the grid function and give it the location like this: lbl.grid(column=0, row=0)

So the complete code will be like this:

Without calling the grid function for the label, it won't show up.

3.3.1 Set label font size

You can set the label font so you can make it bigger and maybe bold. You can also change the font style.

To do so, you can pass the font parameter like this:

```
Note that the font parameter can be passed to any widget to change its font not labels only.

Great, but the window is so small, we can even see the title, what about setting the window size?
```

3.3.2 **Setting window size**

We can set the default window size using geometry function like this:

window.geometry('350x200')

The above line sets the window width to 350 pixels and the height to 200 pixels.

Let's try adding more GUI widgets like buttons and see how to handle the button click event.

3.4 Adding a button widget

Let's start by adding the button to the window, the button is created and added to the window the same as the label:

```
btn = Button(window, text="Click Me")
btn.grid(column=1, row=0)
So our window will be like this:
                                               The result looks like this:
from tkinter import *
                                                 window = Tk()
                                                Hello Click Me
window.title("Welcome to LikeGeeks app")
window.geometry('350x200')
lbl = Label(window, text="Hello")
                                               Note that we place the button on the
lbl.grid(column=0, row=0)
                                               second column of the window which is 1.
btn = Button(window, text="Click Me")
btn.grid(column=1, row=0)
window.mainloop()
```

If you forget and place the button on the same column which is 0, it will show the button only, since the button will be on the top of the label.

3.4.1 Change button foreground and background colors

You can change the foreground for a button or any other widget using **fg** property.

```
Also, you can change the background color for any widget using bg property.

btn = Button(window, text="Click Me", bg="orange", fg="red")

Now, if you tried to click on the button, nothing happens because the click event of the button isn't written yet.
```

3.4.2 Handle button click event

First, we will write the function that we need to execute when the button is clicked:

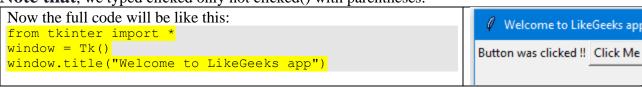

```
def clicked():

lbl.configure(text="Button was clicked !!")
```

Then we will wire it with the button by specifying the function like this:

btn = Button(window, text="Click Me", command=clicked)

Note that, we typed clicked only not clicked() with parentheses.

```
window.geometry('350x200')
lbl = Label(window, text="Hello")
lbl.grid(column=0, row=0)
def clicked():
    lbl.configure(text="Button was clicked !!")
btn = Button(window, text="Click Me", command=clicked)
btn.grid(column=1, row=0)
window.mainloop()
And when we click the button, the result as expected:
```

3.5 Get input using Entry class (Tkinter textbox)

In the previous Python GUI examples, we saw how to add simple widgets, now let's try getting the user input using the Tkinter Entry class (Tkinter textbox).

You can create a textbox using Tkinter Entry class like this:

```
txt = Entry(window, width=10)
```

Then you can add it to the window using grid function as usual

So our window will be like this:

```
from tkinter import *
                                               And the result will be like this:
window = Tk()

∅ Welcome to LikeGeeks app

window.title("Welcome to LikeGeeks app")
window.geometry('350x200')
                                               lbl = Label(window, text="Hello")
lbl.grid(column=0, row=0)
txt = Entry(window, width=10)
txt.grid(column=1, row=0)
def clicked():
lbl.configure(text="Button was clicked !!")
btn = Button(window, text="Click Me", command=clicked)
btn.grid(column=2, row=0)
window.mainloop()
```

Now, if you click the button, it will show the same old message, what about showing the entered text on the Entry widget?

First, you can get entry text using get function. So we can write this code to our clicked function like this:

```
def clicked():
    res = "Welcome to " + txt.get()
    lbl.configure(text= res)
```

If you click the button and there is a text on the entry widget, it will show "Welcome to" concatenated with the entered text.

```
Run the above code and check the
And this is the complete code:
from tkinter import *
                                                result:
window = Tk()
                                                  window.title("Welcome to LikeGeeks app")
window.geometry('350x200')
                                                 Welcome to LikeGeeks LikeGeeks Click Me
lbl = Label(window, text="Hello")
lbl.grid(column=0, row=0)
txt = Entry(window, width=10)
txt.grid(column=1, row=0)
def clicked():
res = "Welcome to " + txt.get()
lbl.configure(text= res)
btn = Button(window, text="Click Me", command=clicked)
btn.grid(column=2, row=0)
window.mainloop()
```

Every time we run the code, we need to click on the entry widget to set focus to write the text, what about setting the focus automatically?

3.5.1 Set focus to the entry widget

That's super easy, all we need to do is to call focus function like this:

txt.focus()

And when you run your code, you will notice that the entry widget has the focus so you can write your text right away.

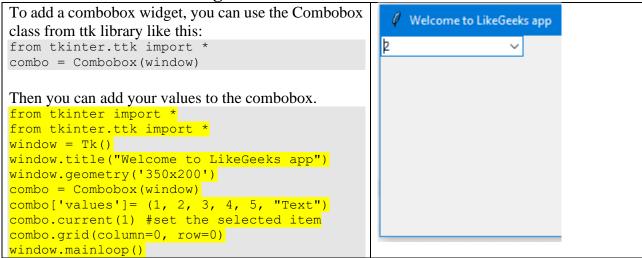

3.5.2 Disable entry widget

To disable the entry widget, you can set the state property to disabled:

txt = Entry(window, width=10, state='disabled')

Now, you won't be able to enter any text.

3.6 Add a combobox widget

As you can see, we add the combobox items using the tuple.

To set the selected item, you can pass the index of the desired item to the current function.

To get the select item, you can use the get function like this:

combo.get()

3.7 Add a Checkbutton widget (Tkinter checkbox)

To create a checkbutton widget, you can use the Checkbutton class like this:

chk = Checkbutton(window, text='Choose')

Also, you can set the checked state by passing the check value to the Checkbutton like this:

```
from tkinter import *
from tkinter.ttk import *
window = Tk()
window.title("Welcome to LikeGeeks app")
window.geometry('350x200')
chk_state = BooleanVar()

chk_state.set(True) #set check state
chk = Checkbutton(window, text='Choose', var=chk_state)
chk.grid(column=0, row=0)
window.mainloop()
```

3.8 Set check state of a Checkbutton

Here we create a variable of type BooleanVar which is not a standard Python variable, it's a Tkinter variable, and then we pass it to the Checkbutton class to set the check state as the highlighted line in the above example.

You can set the Boolean value to false to make it unchecked.

Also, you can use IntVar instead of BooleanVar and set the value to 0 or 1.

```
chk_state = IntVar()
```

```
chk_state.set(0) #uncheck
chk_state.set(1) #check
```

These examples give the same result as BooleanVar.

3.9 Add radio buttons widgets

To add radio buttons, simply you can use RadioButton class like this:

```
rad1 = Radiobutton(window, text='First', value=1)
```

Note that you should set the value for every radio button with a different value, otherwise, they won't work.

```
from tkinter import *
from tkinter.ttk import *
window = Tk()
window.title("Welcome to LikeGeeks app")
window.geometry('350x200')
rad1 = Radiobutton(window, text='First', value=1)
rad2 = Radiobutton(window, text='Second', value=2)
rad3 = Radiobutton(window, text='Third', value=3)
rad1.grid(column=0, row=0)
rad2.grid(column=1, row=0)
rad3.grid(column=2, row=0)
window.mainloop()
```

The result of the above code looks like this:

Also, you can set the command of any of these radio buttons to a specific function, so if the user clicks on any one of them, it runs the function code.

This is an example:

```
rad1 = Radiobutton(window,text='First', value=1, command=clicked)
def clicked():
```

Do what you need

3.9.1 Get radio button value (selected radio button)

To get the currently selected radio button or the radio button value, you can pass the variable parameter to the radio buttons, and later you can get its value.

```
from tkinter import
                                                         Welcome t...
from tkinter.ttk import *
                                                        ● First ○ Second ○ Third Click Me
window = Tk()
window.title("Welcome to LikeGeeks app")
selected = IntVar()
                                                        3
rad1 = Radiobutton(window, text='First', value=1,
     variable=selected)
rad2 = Radiobutton(window, text='Second', value=2,
     variable=selected)
                                                       Every time you select a radio
rad3 = Radiobutton(window,text='Third', value=3,
                                                       button, the value of the
    variable=selected)
                                                       variable will be changed to
def clicked():
                                                       the value of the selected
   print(selected.get())
btn = Button(window, text="Click Me",
                                                       radio button.
    command=clicked)
rad1.grid(column=0, row=0)
rad2.grid(column=1, row=0)
rad3.grid(column=2, row=0)
btn.grid(column=3, row=0)
window.mainloop()
```

3.10 Create a MessageBox

To show a message box using Tkinter, you can use the messagebox library like this:

```
from tkinter import messagebox
messagebox.showinfo('Message title','Message content')
```

Let's show a message box when the user clicks a button.

```
Welcome to LikeGeeks app
from tkinter import *
                                                       Click here
from tkinter import messagebox
window = Tk()
                                                                 Message title
window.title("Welcome to LikeGeeks app")
window.geometry('350x200')
def clicked():
                                                                     Message content
 messagebox.showinfo('Message title', 'Message
 content')
btn = Button(window, text='Click here',
                                                                            OK
command=clicked)
btn.grid(column=0,row=0)
window.mainloop()
                                                       When you click the button, an
                                                       info messagebox will appear.
```

3.10.1 Show warning and error messages

You can show a warning message or error message in the same way. The only thing that needs to be changed is the message function

messagebox.showwarning('Message title', 'Message content') #shows warning message messagebox.showerror('Message title', 'Message content') #shows error message

3.10.2 Show askquestion dialogs

To show a yes no message box to the user, you can use one of the following messagebox functions:

```
from tkinter import messagebox
res = messagebox.askquestion('Message title','Message content')
res = messagebox.askyesno('Message title','Message content')
res = messagebox.askyesnocancel('Message title','Message content')
res = messagebox.askokcancel('Message title','Message content')
res = messagebox.askretrycancel('Message title','Message content')
```

You can choose the appropriate message style according to your needs. Just replace the showinfo function line from the previous line and run it.

Also, you can check what button was clicked using the result variable

If you click **OK** or **yes** or **retry**, it will return **True** value, but if you choose **no** or **cancel**, it will return **False**.

The only function that returns one of three values is **askyesnocancel** function, it returns **True** or **False** or **None**.

3.11 Add a Progressbar widget

To create a progress bar, you can use the progressbar class like this:

```
from tkinter.ttk import Progressbar
bar = Progressbar(window, length=200)
You can set the progress bar value like this:
bar['value'] = 70
```

3.11.1 Change Progressbar color

Changing Progressbar color is a bit tricky, but super easy.

First, we will create a style and set the background color and finally set the created style to the Progressbar.

Check the following example:

```
from tkinter import *
                                                    And the result will be like this:
from tkinter.ttk import Progressbar
                                                        Welcome to LikeGeeks app
from tkinter import ttk
window = Tk()
window.title("Welcome to LikeGeeks app")
window.geometry('350x200')
style = ttk.Style()
style.theme use('default')
style.configure("black.Horizontal.TProgressbar",
      background='black')
bar = Progressbar(window, length=200, style='black.Horizontal.TProgressbar')
bar['value'] = 70
bar.grid(column=0, row=0)
window.mainloop()
```

3.12 Add a filedialog (file & directory chooser)

To create a file dialog (file chooser), you can use the filedialog class like this:

```
from tkinter import filedialog
file = filedialog.askopenfilename()
```

After you choose a file and click open, the file variable will hold that file path.

Also, you can ask for multiple files like this:

```
files = filedialog.askopenfilenames()
```

3.13 Specify file types (filter file extensions)

You can specify the file types for a file dialog using the filetypes parameter, just specify the extensions in tuples.

You can ask for a directory using the askdirectory method:

```
dir = filedialog.askdirectory()
```

You can specify the initial directory for the file dialog by specifying the initialdir like this:

```
from os import path
file = filedialog.askopenfilename(initialdir= path.dirname(__file__))

Easy!!
```

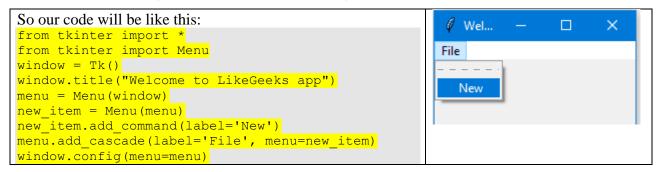

3.14 Add a Menu bar

To add a menu bar, you can use menu class like this:

```
from tkinter import Menu
menu = Menu(window)
menu.add_command(label='File')
window.config(menu=menu)
```

First, we create a menu, then we add our first label, and finally, we assign the menu to our window. You can add menu items under any menu by using add cascade() function like this:

menu.add_cascade(label='File', menu=new_item)

```
window.mainloop()
```

Using this way, you can add many menu items as you want.

```
from tkinter import *

∅ Wel...

                                                        ×
from tkinter import Menu
window = Tk()
                                         File
window.title("Welcome to LikeGeeks
app")
                                           New
menu = Menu(window)
new item = Menu(menu)
                                           Edit
new_item.add_command(label='New')
new item.add separator()
new item.add command(label='Edit')
menu.add cascade(label='File',
  menu=new item)
window.config(menu=menu)
window.mainloop()
```

Here we add another menu item called Edit with a menu separator.

You may notice a dashed line at the beginning, well, if you click that line, it will show the menu items in a small separate window.

You can disable this feature by disabling the tearoff feature like this:

```
new_item = Menu(menu, tearoff=0)
```

Just replace the new_item in the above example with this one and it won't show the dashed line anymore.

I don't need to remind you that you can type any code that works when the user clicks on any menu item by specifying the command property.

new_item.add_command(label='New', command=clicked)
